

Interpretability, Explainability, and Fairness in Machine Learning Models

Gonzalo Rivero

September, 24 2020

Introduction

Goals for today

- ▶ Discuss general concepts with Rudin (2019) as starting point
- ▶ Explore two/two-and-a-half core ideas:
 1. Interpretability
 2. Explainability
 3. Fairness (+ causality!)
- ▶ Question: **Should we use ML for high-stakes decisions?**
- ▶ Follow-up: **How to make sure it is not doing a bad thing?**
- ▶ Goal is to raise awareness of this literature.
- ▶ No technical details or how-to.

Interpretability and explainability

Context

- ▶ Two standard types of cases have brought back the literature:

1. COMPAS:

- ▶ A “decision support tool” used to predict recidivism.
- ▶ Scores can be considered by judges during sentences.
- ▶ Proprietary software which cannot be examined by the public.
- ▶ Evaluation by ProPublica showed that it depended on race.
- ▶ “Blacks are almost twice as likely to be labelled as higher risk”

2. Algorithmic hiring:

- ▶ ML models through all the pipeline
 - ▶ Who sees the ads
 - ▶ Expected performance of the applicant
 - ▶ Which applicants will receive more screening
 - ▶ Forecast salary
 - ▶ Evidence of reproduction of human biases
-
- ▶ “Right to explanation” in the GDPR

Interpretability vs. explainability

- ▶ The *tentative* definitions are:
 - ▶ “High stakes” → “Impact on society”
 - ▶ “The bad thing” → “automation of discrimination”
- ▶ Problem is that models are “black boxes”
- ▶ This suggests two/three approaches:
 1. Simplify (*constraint*) the model to make it easier to *interpret*
 2. Build tools to make a complicated models easier to *explain*
 3. (Maybe) develop criteria to assess the model predictions
- ▶ Rudin (2019) suggests that 1. is strictly superior *and feasible*

Why explainability

- ▶ We want interpretability because it:
 1. Engineers trust
 2. May uncover causal relations
 3. It addresses the right to explanation
- ▶ An interpretable model is
 1. Open (as opposed to proprietary)
 2. Intelligible
- ▶ Not what ML optimizes for!
 - ▶ Performance metrics do not sufficiently characterize the model
- ▶ Alternative is to do post-hoc interpretation

Why not explainability?

1. There is no trade-off between accuracy and interpretability
 - ▶ At least not with structured data and meaningful features
 - ▶ Lasso performs as well as RF/GBM in many domains
 - ▶ Interpretability allows us to improve feature construction
2. Explanations are not faithful to the model
 - ▶ By construction (otherwise, the explanation is the model)
 - ▶ No guarantee that the explanation is correct
 - ▶ Should we trust the explanation or the model?
 - ▶ Does COMPAS really base the predictions on race?
3. Ripe for procedural error
 - ▶ Models are hard to troubleshoot

Why not interpretable models?

- ▶ Why haven't we seen more interpretable models?
- 1. Companies cannot benefit from them
 - ▶ Transparency is a property of them *and the ownership*
 - ▶ Disconnect between profits and responsibility for predictions
- 2. Interpretable models are harder
 - ▶ Unlike off-the-shelf ML approach
 - ▶ May require domain expertise
- 3. Black box lead to discovery
 - ▶ Reverse direction from data to theory

Why are interpretable models harder?

- ▶ We associate interpretability with
 1. Linear models
 - ▶ Weighted combinations are nice
 - ▶ Integer combinations are even nicer
 - ▶ Very easy as scoring
 - ▶ NP-complete
 2. If-then rules
 - ▶ Current trees use greedy heuristics
 - ▶ We would like globally optimal trees
 - ▶ That also minimize complexity (f.i. leaves)
 - ▶ NP-complete
 3. Case-based reasoning
 - ▶ Interpretability is domain specific
 - ▶ Not clear what it means in general
 - ▶ We may have different heuristics for different problems
 - ▶ Interpretability is like performance

But what is interpretability?

- ▶ We could have several goals all of them challenging.
 - ▶ Trust. We want models that we can trust. But is that...
 - ▶ ... confidence in performance? How often is right
 - ▶ ... willingness to relinquish control? When is it right
 - ▶ Causality. We want relations to have causal meaning
 - ▶ Impossible without a theoretical model
 - ▶ Transferability. Models should not depend on the environment
 - ▶ Possibility of gaming
 - ▶ Limited generalizability beyond train distribution
 - ▶ Informativeness
 - ▶ Provide insights to decision makers
 - ▶ Learn the structure of the data
 - ▶ Isn't a explainable model better?
 - ▶ Fair and ethical decision making
 - ▶ Not the metric we use

Is interpretability undesirable?

- ▶ Let's consider the properties of interpretable models
 - ▶ Simulatability
 - ▶ The model can be contemplated at once (i.e., simplicity)
 - ▶ “Lasso is more interpretable than an NN”
 - ▶ Is that about model size or computation for inference?
 - ▶ A subjective statement about limits of cognition
 - ▶ How many dimensions before a tree is not interpretable?
 - ▶ Decomposability
 - ▶ Input, parameters and calculations are interpretable
 - ▶ Manual feature is more interpretable than automatic ones
 - ▶ But they are much less robust
 - ▶ Transparency
 - ▶ Are models less transparent than humans?
 - ▶ Any model is replicable
- ▶ Interpretability is a subjective goal

Fairness

Fairness in Machine Learning

- ▶ Ignore the model, think about the predictions
 - ▶ The predictions should be “fair”
 - ▶ Standard question since the 1960s in education research
- ▶ Related to the notion of non-discrimination
 - ▶ Procedural fairness
 - ▶ Outcome equalization
 - ▶ These two principles may enter in conflict
 - ▶ See Ricci vs. DeStefano
- ▶ “No fairness through unawareness”
 - ▶ Removing the protected attribute is not enough
 - ▶ Formal vs. intentional disparate treatment
 - ▶ Ignore biases in data vs. Induce biases in data

Advantages of fairness as a concept

- ▶ Suitable for a operational definition
 - ▶ Covariates/features
 - ▶ A protected attribute
 - ▶ A decision rule
- ▶ Suitable for guiding model corrections
 - ▶ In pre-processing (uncorrelate feature space)
 - ▶ In training (customize loss function)
 - ▶ In post-processing (adjust the predictions)

But what is fairness?

Standard formal criteria (attribute A , score R , target Y)

- ▶ Independence: $R \perp A$
 - ▶ Acceptance rate should be equal across groups
 - ▶ Condition can be met without fairness
 - ▶ Accept at same rate but use different procedures
 - ▶ Easy to satisfy and verify
- ▶ Separation: $R \perp A|Y$
 - ▶ Correlation between R and A is justified by Y
 - ▶ Equalization of FPR and FNR across groups
 - ▶ $FPR = \Pr\{R = 1|Y = 1\}$; $FNR = \Pr\{R = 1|Y = 0\}$
 - ▶ You can choose which one to relax
 - ▶ Dealt with in ROC
- ▶ Sufficiency: $Y \perp A|R$
 - ▶ Parity of positive/negative predicted values
 - ▶ The score is calibrated *by group*
 - ▶ Usually does not require intervention

Challenges

- ▶ Impossibility theorems
 - ▶ No two criteria can be simultaneously satisfied
 - ▶ COMPAS debate between Northpointe and ProPublica
 - ▶ ProPublica: COMPAS violates separation
 - ▶ Northpointe: COMPAS satisfies sufficiency
 - ▶ Guidance cannot come only from data
- ▶ Observability and inference
 - ▶ All the criteria are observational (no *what-if*)
 - ▶ Depends on a causal graph
 - ▶ Can build identical joint distributions with different fairness
 - ▶ Observational definition cannot distinguish them
 - ▶ Answers cannot depend only on observational data

Conclusions

Conclusions

- ▶ “New” fields that have grown considerably
 - ▶ Complicated to navigate
 - ▶ Sometimes very technical and inaccessible
 - ▶ Disparate languages across fields
- ▶ Many new available tools
 - ▶ Will discuss some in the third session
- ▶ Clear business impact
 - ▶ Increasing application of ML for social outcomes
 - ▶ Performing ML or auditing ML
 - ▶ Leverage the company's SME
- ▶ More practical motivation
 - ▶ What is your model capturing?
 - ▶ Does it do what you think it does?
 - ▶ Interpretation/explanation matters for validity
